# Chapter 1

## Numbers and Sets

### 1.1 Introduction to number systems and logic

### 1.2 Sets, relations and functions

#### 1.2.1 Union, intersection and equality of sets

#### 1.2.2 Indicator functions

#### 1.2.3 Functions

#### 1.2.4 Relations and equivalence relations

#### 1.2.5 The Inclusion-Exclusion Principle

### 1.3 The integers

#### 1.3.1 Natural numbers

### 1.4 Elementary number theory

#### 1.4.1 Prime numbers

**Definition 1.4.1.** For two integers  $a$  and  $b$ ,  $a$  *divides*  $b$  if there exists an integer  $k$  such that  $b = ak$ . We call  $a$  a *factor* of  $b$  and write  $a \mid b$ .

**Definition 1.4.2.** A number  $p$  is *prime* if its divisors are only 1 and itself. A number which is not prime is called a *composite* number.

**Theorem 1.1.** Every number greater than 1 has a prime factor.

*Proof.* We proceed by induction. Note that 2 obviously has a prime factor 2. Suppose that every number less than  $m$  has a prime factor, we need to show that  $m$  also has a prime

factor. If  $m$  is prime then we are done. If  $m$  is not prime then there exists  $a, b \in \mathbb{N}$  with  $a \leq m$  such that  $ab = m$  and  $a \neq 1$ . Then by the hypothesis,  $a$  has a prime factor. That prime factor must also divide  $m$ . Thus every number greater than 1 has a prime factor.  $\square$

This proof of infinitude of prime is first described by Euclid.

**Theorem 1.2.** There are infinitely many prime numbers.

*Proof.* Suppose there are only finitely many prime numbers, denoted  $p_1, \dots, p_k$ . Consider the number obtained by multiplying all primes in the list, and then adding one;  $p_1 p_2 \cdots p_k + 1$ . This number is obviously greater than 1, and so it must have a prime factor  $q$ . It then follows that  $q$  must be one of the finitely many primes in the list. But for all  $p_i$  with  $1 \leq i \leq k$ ,  $p_i \nmid p_1 p_2 \cdots p_k + 1$ . This means that  $q$  is not equal to any of the prime in the list, a contradiction.  $\square$

### 1.4.2 Euclid's algorithm

### 1.4.3 Solution in integers of $ax + by = c$ .

### 1.4.4 Modular arithmetic

### 1.4.5 Chinese remainder theorem

### 1.4.6 Wilson's theorem

## 1.5 The real numbers

### 1.5.1 Least upper bounds

### 1.5.2 Sequences and series

### 1.5.3 Irrationality of $\sqrt{2}$ and $e$

What does it mean for a number to be rational? Recalls the definition of a rational number, which says that a number  $a$  is rational if it can be expressed in the form

$$a = \frac{p}{q}$$

for relatively prime integers  $p, q$  with  $q \neq 0$ .

We start by the classic proof of irrationality of  $\sqrt{2}$ .

**Theorem 1.3.**  $\sqrt{2}$  is irrational.

*Proof.* Suppose  $\sqrt{2}$  is rational, and  $\sqrt{2} = \frac{p}{q}$  with  $(p, q) = 1$  and  $q \neq 0$ . Then  $(\sqrt{2})^2 = 2 = \frac{p^2}{q^2}$ , so  $2q^2 = p^2$ . Therefore  $2 \mid p^2$ ; it follows that  $p$  is even. But then  $p = 2p_0$  for some integer  $p_0$ , which means that  $q^2 = 2(p_0)^2$  and  $q$  is even. But this contradicts our assumption that  $p$  and  $q$  are relatively prime.  $\square$

More generally,

**Theorem 1.4.**  $\sqrt{p}$  is irrational if  $p$  is prime.

*Proof.* We provide another proof using unique factorisation of integers. Assume that  $\sqrt{p}$  is a rational number, and that  $\sqrt{p} = \frac{a}{b}$ , with coprime  $a, b$  and  $b \neq 0$ . If  $b = 1$ , then  $p$  must divide  $a^2$ , then it divides  $a$ , which is absurd. Then there exists a prime  $q$  in the factorisation of  $b$  such that  $q \nmid a$ , or else they have a common factor.

Now consider  $2 = \frac{a^2}{b^2}$ .  $a^2$  is factored into the product of primes of  $a$ , but squared. The prime factor of  $b^2$  includes  $q^2$ . As so the fraction  $\frac{a^2}{b^2}$  cannot be reduced to an integer, contradicting  $2 = \frac{a^2}{b^2}$ .  $\square$

We can extend the result to the following theorem.

**Theorem 1.5.**  $\sqrt{\frac{p}{q}}$  is rational if and only if  $p$  and  $q$  are perfect squares.

Even more generally,

**Theorem 1.6.** If an integer  $a$  is not an exact  $k$ -th power of another integer then  $\sqrt[k]{a}$  is irrational.

We now provide a proof that  $e$  is irrational, starting with the definition of  $e$ .

**Definition 1.5.1.** The number  $e$  is defined as

$$e = \sum_{n=0}^{\infty} \frac{1}{n!} = \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n}\right)^n.$$

We will show later on that the two definition is indeed equal. The proof of irrationality of  $e$  will use the fact that

$$e = \sum_{n=0}^{\infty} \frac{1}{n!} = 1 + \frac{1}{1!} + \frac{1}{2!} + \frac{1}{3!} + \cdots.$$

Note that  $2 = 1 + 1 < e = 1 + \frac{1}{1!} + \frac{1}{2!} + \frac{1}{3!} + \cdots < 1 + \left(1 + \frac{1}{2} + \frac{1}{2^2} + \frac{1}{2^3} + \cdots\right) = 3$ , that is  $e$  is bounded between 2 and 3. Now we present the proof of irrationality of  $e$ , as presented by Joseph Fourier.

**Theorem 1.7.**  $e$  is irrational.

*Proof.* Suppose  $e$  is rational and with usual condition  $(a, b) = 1$ ,  $e = \frac{a}{b}$ . Define

$$x = b! \left( e - \sum_{n=0}^b \frac{1}{n!} \right). \quad (1.1)$$

This renders  $x$  an integer, for if we substitute  $e = \frac{a}{b}$ ,

$$x = b! \left( \frac{a}{b} - \sum_{n=0}^b \frac{1}{n!} \right) = a(b-1)! - \sum_{n=0}^b \frac{b!}{n!}.$$

For  $0 \leq n \leq b$ ,  $n!$  divides entirely into  $b!$ , and so the sum is an integer.

Notice that we are using an idea that the difference between the fast-converging series expansion of  $e$  and  $\sum_{n=0}^b \frac{1}{n!}$  multiplied by  $b!$  is still less than 1, thus making  $x$  an integer between 0 and 1. This would give us a contradiction.

Let's bound  $x$  first by showing that it is indeed positive, since

$$x = b! \left( e - \sum_{n=0}^b \frac{1}{n!} \right) = b! \left( \sum_{n=0}^{\infty} \frac{1}{n!} - \sum_{n=0}^b \frac{1}{n!} \right) = \sum_{n=b+1}^{\infty} \frac{b!}{n!}, \quad (1.2)$$

and all of its terms is positive, so  $x > 0$ .

Consider  $b!/n!$ . For all term  $n \geq b+1$ ,

$$\frac{b!}{n!} = \frac{1}{(b+1)(b+2) \cdots (b+(n-b))} < \frac{1}{(b+1)^{n-b}}.$$

The inequality is strict for  $n > b+1$ , we now have

$$x = \sum_{n=b+1}^{\infty} \frac{b!}{n!} < \sum_{n=b+1}^{\infty} \frac{1}{(b+1)^{n-b}} = \sum_{k=1}^{\infty} \frac{1}{(b+1)^k} = \frac{1}{b+1} \left( \frac{1}{1 - \frac{1}{b+1}} \right) = \frac{1}{b} < 1. \quad (1.3)$$

A contradiction. □

Later in the 19th century,  $e$  is proven to be transcendental, i.e.  $e$  is not a root of any polynomial with rational coefficient, by Charles Hermite. Furthermore the result of the Lindemann-Weierstrass theorem indicates that  $e^a$  is transcendental if  $a$  is rational and non-zero. The same theorem also shows that  $\pi$  is transcendental.

# Chapter 2

## Groups

### 2.1 Examples of groups

#### 2.1.1 Axioms for groups

**Definition 2.1.1.** A *group* is a set  $G$ , together with a binary operation  $*$  on  $G$  with the following properties.

1. (Closure) for all  $g$  and  $h$  in  $G$ ,  $g * h \in G$ ;
2. (Associativity) for all  $f, g$  and  $h$  in  $G$ ,  $g * h \in G$ ,  $f * (g * h) = (f * g) * h$ ;
3. (Existence of identity) there is a unique  $e$  in  $G$  such that for all  $g$  in  $G$ ,  $g * e = g = e * g$ ;
4. (Existence of inverse) if  $g \in G$  there is some  $h$  in  $G$  such that  $g * h = e = h * g$ .

These results follow nicely.

**Lemma 2.1.1.** Let  $G$  be any group. Then, given  $g \in G$ , there is only one element  $h$  such that  $g * h = e = h * g$ . Particularly  $(g^{-1})^{-1} = g$ .

**Lemma 2.1.2** (Cancellation law). Suppose that  $a, b$  and  $x$  are in a group  $G$ . If  $a * x = b * x$  then  $a = b$ .

**Lemma 2.1.3.** Suppose that  $a$  and  $b$  are in a group  $G$ . Then the equation  $a * x = b$  has a unique solution  $x = a^{-1} * b$ .

**Lemma 2.1.4.** In any group  $G$ ,  $e$  is the unique solution of  $x * x = x$ .

Notice that we do not include the familiar assumption that  $f * g = g * f$  normally found in arithmetic. In fact, for some interesting groups this equality does not hold.

**Definition 2.1.2.** Let  $G$  be a group with respect to  $*$ . The elements  $f$  and  $g$  *commute* if  $f * g = g * f$ . We call  $G$  *abelian* if for all  $f$  and  $g$  in  $G$ , we have  $f * g = g * f$ .

We adopt the notation  $gh$  as equivalent to  $g * h$  for simplicity.

### 2.1.2 Examples from geometry

In this section we examine the idea of group in geometry, using polygons.

### 2.1.3 Permutation on a set

In this section we will show that permutations of a non-empty set  $X$ , in fact, form a group, starting with the definition of permutations acting on a set, although only for finite sets, before developing the idea further into arbitrary sets.

**Definition 2.1.3.** A *permutation*  $\alpha: X \rightarrow X$  is a bijection from  $X$  to itself. We say that  $\alpha$  acts on the set  $X$ . The set of all permutations of  $X$  is denoted  $\mathcal{P}(X)$ .

This set is indeed a group.

**Theorem 2.1.** The set  $\mathcal{P}(X)$  forms a group under composition of functions. We shall write  $\alpha\beta(x)$  in place of  $\alpha(\beta(x))$ .

*Proof.* We will show that all group axioms are satisfied.

1. It is obvious that if  $\alpha, \beta$  are permutations, then  $\alpha\beta$  is also a permutation. Thus the set  $\mathcal{P}(X)$  is closed under composition.
2. For any permutations  $\alpha, \beta, \gamma$ , let  $\mu = \alpha\beta$  and  $\nu = \beta\gamma$ . Then for every  $x$  in  $X$ ,

$$\begin{aligned}
 (\alpha(\beta\gamma))(x) &= (\alpha\nu)(x) \\
 &= \alpha(\nu(x)) \\
 &= \alpha(\beta(\gamma(x))) \\
 &= \mu(\gamma(x)) \\
 &= (\mu\gamma)(x) \\
 &= ((\alpha\beta)\gamma)(x).
 \end{aligned} \tag{2.1}$$

Thus the permutations are associative under composition.

3. The identity permutation  $\iota(x) = x$  is the identity of  $\mathcal{P}(X)$ , since  $\alpha\iota(x) = \alpha(x) = \iota\alpha(x)$ .
4. For any element  $\alpha$  of  $\mathcal{P}(X)$ , the inverse is simply its functional inverse  $\alpha^{-1}$ . Direct verification shows that  $\alpha\alpha^{-1} = \iota = \alpha^{-1}\alpha$ .

□

The above proof lets us write  $\alpha\beta\gamma$  for any composition of three or more permutations without any confusion.

Setting  $X = \{1, \dots, n\}$ , the study of permutation groups is simpler. We shall give a name for such group.

**Definition 2.1.4.** The *symmetric group*  $S_n$  is a set of permutations of  $\{1, \dots, n\}$ . We say that the group is of degree  $n$ .

**Theorem 2.2.** The order of  $S_n$  is  $n!$ .

*Proof.* Evidently, there are  $n!$  permutations on a set with  $n$  elements. □

We now introduce a customary notation for permutation  $\rho(x)$  in the form

$$\rho = \begin{pmatrix} 1 & 2 & 3 & \cdots & n \\ \rho(1) & \rho(2) & \rho(3) & \cdots & \rho(n) \end{pmatrix},$$

which mean that the image of the permutation  $\rho(i)$  is underneath  $i$  in the first row. For example, let  $\alpha$  be a permutation on  $\{1, 2, 3, 4\}$  with  $\alpha(1) = 1, \alpha(2) = 4, \alpha(3) = 2$  and  $\alpha(4) = 3$ , then

$$\alpha = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 1 & 4 & 2 & 3 \end{pmatrix}.$$

**Example 2.1.1.** There are 6 permutations in  $S_3$ , they are

$$\begin{pmatrix} 1 & 2 & 3 \\ 1 & 2 & 3 \end{pmatrix}, \begin{pmatrix} 1 & 2 & 3 \\ 1 & 3 & 2 \end{pmatrix}, \begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 3 \end{pmatrix}, \begin{pmatrix} 1 & 2 & 3 \\ 2 & 3 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 2 & 3 \\ 3 & 1 & 2 \end{pmatrix}, \begin{pmatrix} 1 & 2 & 3 \\ 3 & 2 & 1 \end{pmatrix}.$$

Note that

$$\begin{pmatrix} 1 & 2 & 3 \\ 1 & 3 & 2 \end{pmatrix} \begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 3 \end{pmatrix} = \begin{pmatrix} 1 & 2 & 3 \\ 3 & 1 & 2 \end{pmatrix} \neq \begin{pmatrix} 1 & 2 & 3 \\ 2 & 3 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 3 \end{pmatrix} \begin{pmatrix} 1 & 2 & 3 \\ 1 & 3 & 2 \end{pmatrix}.$$

Therefore  $S_3$  is not abelian. More generally  $S_n$  is not abelian for  $n \geq 3$ . We will study permutations in more details later on.

### 2.1.4 Subgroups and homomorphisms

**Definition 2.1.5.** A *subgroup* of a group  $G$  is a subset of  $G$  which itself form a group under the operation taken from  $G$ .

**Theorem 2.3.** Let  $H$  be a subgroup of  $G$ , then the identity element of  $H$  is that of  $G$ .

A group  $G$  always at least admits two subgroup, namely  $G$  and the singleton  $\{e\}$ . We call  $\{e\}$  the *trivial subgroup* of  $G$ , and we say that  $H$  is the *non-trivial subgroup* of  $G$  if  $H \neq \{e\}$ . We say that  $H$  is a *proper subgroup* of  $G$  if  $H \neq G$ .

We now give a test for a subset to be a subgroup.

**Theorem 2.4** (A test for subgroup). Let  $G$  be a group, and  $H$  be a non-empty subset of  $G$ . Then  $H$  is a subgroup of  $G$  if and only if

1. if  $g \in H$  and  $h \in H$ , then  $gh \in H$ , and
2. if  $g \in H$  then  $g^{-1} \in H$ .

Another test is similar and follows from the above theorem.

**Theorem 2.5.** Let  $G$  be a group, and  $H$  be a non-empty subset of  $G$ . Then  $H$  is a subgroup of  $G$  if and only if  $xy^{-1} \in H$  whenever  $x, y \in H$ .

**Example 2.1.2.** The group  $(\mathbb{Z}, +)$  is a subgroup of  $(\mathbb{R}, +)$ .

The following property of the class of subsets of  $G$  is important.

**Theorem 2.6.** Let  $G$  be any group, then the intersection of any collection of subgroups of  $G$  is itself a subgroup of  $G$ .

*Proof.* Note that the intersection  $\cap_t H_t$  of the subgroups of  $G$ , defined as  $H_t$  for some  $t$  in the index set  $T$ , is not empty. Then for every elements  $g \in \cap_t H_t$  and  $h \in \cap_t H_t$ , they also lie in  $H_t$  for every  $t$ . And thus  $gh \in H_t$ , so  $gh \in \cap_t H_t$ . Any element  $g \in \cap_t H_t$  also has its inverse in every subgroup  $H_t$ . It then follows that  $g^{-1} \in \cap_t H_t$ . Therefore  $\cap_t H_t$  forms a subgroup under the operation of  $G$ .  $\square$

As a consequence, we see that for any non-empty subset  $G_0$  of  $G$ , we can consider the intersection of the collection of all subgroups  $H$  of  $G$  than contain  $G_0$ . The collection is not empty, since  $G$  is itself in the collection. It follows that the intersection is itself not empty, and is a subgroup of  $G$  that contain  $G_0$ . In fact, it is the *smallest subgroup* to contain  $G_0$ . This allows us to propose the next definition.

**Definition 2.1.6.** Let  $G_0$  be a non-empty subset of a group  $G$ . The subgroup of  $G$  generated by  $G_0$  is the smallest subgroup of  $G$  that contains  $G_0$ .

The idea of subgroup is expanded into the notion of a **coset**, which will be explored later.

Let's now turn to *homomorphism*, as a tool to study relationship between two groups.

**Definition 2.1.7.** Let  $G, H$  be groups. A function  $\phi: G \rightarrow H$  is a *homomorphism* if it takes the action of  $G$  to that of  $H$ , namely

$$\phi(xy) = \phi(x)\phi(y),$$

for all  $x, y \in G$ .

**Definition 2.1.8.** A homomorphism  $\phi$  is called an *isomorphism* if it is bijective.

**Lemma 2.1.5.** The homomorphism  $\phi: G \rightarrow H$  sends the identity of  $G$  to that of  $H$ .

*Proof.* Let  $x = y = e_G$ . So  $\phi(e_G) = \phi(e_G)\phi(e_G)$ . This equation is satisfied only when  $\phi(e_G) = e_H$ .  $\square$

**Lemma 2.1.6.**  $\phi(xy^{-1}) = \phi(x)\phi(y)^{-1}$ .

*Proof.* This is clear from the fact that  $\phi(y)\phi(xy^{-1}) = \phi(x)$ .  $\square$

**Lemma 2.1.7.**  $\phi(x^{-1}) = \phi(x)^{-1}$ .

**Lemma 2.1.8.** If  $\phi: G \rightarrow H$  and  $\theta: H \rightarrow K$  are homomorphisms, then  $\theta\phi: G \rightarrow K$  is also a homomorphism. Similarly, if  $\phi: G \rightarrow H$  and  $\theta: H \rightarrow K$  are isomorphisms, then  $\theta\phi: G \rightarrow K$  is an isomorphism.

The idea of kernel, introduced for vector spaces, motivates us to find an analogy for homomorphisms between groups. As the kernel of a linear map is the set of vectors mapped to the identity elements of the image spaces, we naturally define kernel as follows.

**Definition 2.1.9.** The *kernel*  $\ker \phi$  of a homomorphism  $\phi: G \rightarrow H$  is the set of elements of  $G$  mapped to the identity of  $H$ , that is,

$$\{g \in G: \phi(g) = e_H\}.$$

**Theorem 2.7.** Let  $\phi: G \rightarrow H$ . Then  $\ker \phi$  is a subgroup of  $G$ .

This result is similar to those of kernels of vector spaces.

### 2.1.5 Symmetry groups

## 2.2 The Möbius group

We first begin with the definition of Möbius transformation.

**Definition 2.2.1.** A *Möbius transformation* is a function  $f$  of a complex variable  $z$  in the form

$$f(z) = \frac{az + b}{cz + d},$$

for some complex numbers  $a, b, c$  and  $d$ , with the condition that  $ad - bc \neq 0$ .

The condition  $ad - bc \neq 0$  might not be obvious, but it follows from the fact that

$$f(z) - f(w) = \frac{(ad - bc)(z - w)}{(cz + d)(cw + d)}.$$

If  $ad - bc = 0$ , then  $f$  is constant. This also shows that  $f$  is injective.

This definition of the Möbius transformation has two problems. First, a Möbius transformation  $f$  is not unique. As for example, the 4-tuples  $(a, b, c, d)$  and  $(ma, mb, mc, md)$  with  $m \neq 0$  will all map a complex number  $z$  to a same number. Thus, given  $f$ , we *cannot* say what are the coefficients.

The second problem stems from the fact that, for example  $1/(z - z_0)$  is not defined at the point  $z_0$ . This means that there is no subset of  $\mathbb{C}$  on which all Möbius maps are defined.

Here is an example of this.

**Example 2.2.1.** Let  $f(z) = (z + 2)/z$  and  $g(z) = (z + 1)/(z - 1)$ . Then,

$$f(g(z)) = \frac{g(z) + 2}{g(z)} = \frac{(z + 1) + 2(z - 1)}{z + 1} = \frac{3z - 1}{z + 1},$$

so that  $fg$  fixes the point 1. However,  $g$  is not defined when  $z = 1$ . What's worse is that, if  $h(z) = 1/z$  then  $hfg(z) = (z+1)/(3z-1)$ , although  $g$  is not defined when  $z = 1$ ,  $fg(z)$  is not defined when  $z = -1$ , and  $hfg(z)$  is not defined when  $z = 1/3$ . More generally, a composition  $f_1 \cdots f_n$  of Möbius maps will not be defined at  $n$  distinct points in the complex plane.

The following theorem addresses the first problem.

**Theorem 2.8.** Suppose that  $a, b, c, d, \alpha, \beta, \gamma$  and  $\delta$  are complex numbers with  $(ad - bc)(\alpha\delta - \beta\gamma) \neq 0$ , and such that for at least three distinct values of  $z$  in  $\mathbb{C}$ ,  $cz + d \neq 0$ ,  $\gamma z + \delta \neq 0$ , and

$$\frac{az + b}{cz + d} = \frac{\alpha z + \beta}{\gamma z + \delta}.$$

Then there is some non-zero complex number  $\lambda$  such that

$$\begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} = \lambda \begin{pmatrix} a & b \\ c & d \end{pmatrix}. \quad (2.2)$$

*Proof.* Consider the quadratic polynomial

$$(az + b)(\gamma z + \delta) = (\alpha z + \beta)(cz + d).$$

The polynomial has three distinct roots, and so it must be a zero polynomial. Therefore,  $a\gamma = c\alpha$ ,  $b\gamma + a\delta = c\beta + d\alpha$  and  $b\delta = d\beta$ , which is equivalent to

$$\begin{pmatrix} d & -b \\ -c & a \end{pmatrix} \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} = \begin{pmatrix} \mu & 0 \\ 0 & \mu \end{pmatrix},$$

where  $\mu^2 = (ad - bc)(\alpha\delta - \beta\gamma) \neq 0$ . We then have

$$\begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} = \frac{\mu}{ad - bc} \begin{pmatrix} a & b \\ c & d \end{pmatrix}.$$

□

The first problem is then resolved by showing that the 4-tuple  $(a, b, c, d)$  determines  $f$ , up to non-zero multiple. The second problem will be resolved differently, by joining an extra point, which is called *the point at infinity* to  $\mathbb{C}$ . This point is denoted  $\infty$ .

**Definition 2.2.2.** The set of complex numbers joined with the set  $\{\infty\}$  of the point at infinity is called an *extended complex plane*, and is denoted  $\mathbb{C}_\infty$ .

We already have our notion of the Möbius map approaching infinity, since we have

$$\lim_{z \rightarrow \infty} \frac{az + b}{cz + d} = \frac{a}{c}, \quad \lim_{z \rightarrow -d/c} \frac{az + b}{cz + d} = \infty$$

when  $c \neq 0$ . And if  $c = 0$  then  $\lim_{z \rightarrow \infty} f(z) = \infty$ . So we naturally use them to assign value to  $f(\infty)$ .

**Definition 2.2.3.** For  $c \neq 0$ , define  $f(\infty) = a/c$  and  $f(-d/c) = \infty$ . If  $c = 0$  then  $f(\infty) = \infty$ .

This assignment of values is well-defined only because we have shown before that either  $c \neq 0$  or  $c = 0$ , and if  $c \neq 0$  then the value of  $a/c$  and  $-d/c$  is always the same for any multiple of  $c$ . The main result of this definition is that, all Möbius transformations are now defined on the set  $\mathbb{C}_\infty$  so that the composition of any two Möbius maps is defined. In fact,

**Theorem 2.9.** Every Möbius map is a bijection from  $\mathbb{C}_\infty$  onto itself, and that they form the Möbius group  $\mathcal{M}$  with respect to composition.

**Theorem 2.10.** Every Möbius map transformation can be expressed as the composition of at most four maps, which are

1. rotation and dilation of the form  $z \mapsto az$ ,
2. translation of the form  $z \mapsto z + b$ ; and
3. *complex inversion* of the form  $z \mapsto 1/z$ .

There is a connection between Möbius maps and  $2 \times 2$  complex matrices. We have seen that, if  $M$  is a non-singular  $2 \times 2$  matrix with complex entries, then we can find a corresponding Möbius map  $f$ . Indeed this mapping, explicitly stated

$$\phi: \begin{pmatrix} a & b \\ c & d \end{pmatrix} \mapsto f, \quad f(z) = \frac{az + b}{cz + d},$$

gives us a homomorphism between the group of  $2 \times 2$  non-singular complex matrices  $\text{GL}(2, \mathbb{C})$  and  $\mathcal{M}$ .

**Theorem 2.11.** The mapping  $\phi$  is a homomorphism from the group  $\text{GL}(2, \mathbb{C})$  onto the Möbius group  $\mathcal{M}$ .

**Lemma 2.2.1.** The kernel of  $\phi$  is  $\{\lambda I: \lambda \in \mathbb{C}\}$ . where  $I$  is the identity matrix.

### 2.2.1 Fixed points and uniqueness

### 2.2.2 Cross-ratios

### 2.2.3 Preservation of circles

### 2.2.4 Conjugation

### 2.2.5 Fixed points of Möbius maps and iteration

## 2.3 Lagrange's theorem

### 2.3.1 Cosets

We have introduced the idea of subgroup in the previous section. Now we come to the idea of constructing a subset of any group  $G$  from its subgroup. For example, we could

define a new subset  $XY$  of  $G$  by

$$XY = \{xy : x \in X, y \in Y\}$$

for any subgroup  $X, Y$  of  $G$ . If  $X$  is a singleton, that is  $X = \{x\}$ , we shall adopt a notation  $XY = xY$ . Such constructions which we shall consider are of the form

$$gH = \{gh : h \in H\} \text{ or } Hg = \{hg : h \in H\}$$

for some  $g \in G$ , and  $H$  is a subgroup of  $G$ . The set  $gH$  is called the *left coset* of  $H$  with respect to  $g$ , similarly,  $Hg$  is the *right coset* of  $H$  with respect to  $g$ . Some constructions of this type might turn out to be the same set  $H$ . This is illustrated below.

**Theorem 2.12.** Let  $H$  be a subgroup of  $G$ , and  $g \in G$ . Then  $g \in H$  if and only if  $gH = H$  (or  $Hg = H$ ).

Thus we concern ourselves to the study of  $gH$  when  $g \notin H$ . We will adopt an additive notation  $g + H$  in place of  $gH$  when such subgroups employ addition. The next results show that a group can be divided into disjoint cosets. This is called the *coset decomposition* of  $G$ .

**Theorem 2.13.** Let  $H$  be a subgroup of a group  $G$ , then  $G$  is a union of its left (or right) cosets.

*Proof.* Clearly, for any  $g \in G$ ,  $g \in gH$ . So  $g$  is contained in the union. □

**Theorem 2.14.** Let  $H$  be a subgroup of a group  $G$ , then any two left cosets of  $G$  are either equal or disjoint.

*Proof.* Let  $f, g \in G$  and  $fH, gH$  are the two left cosets. Suppose that  $fH$  and  $gH$  are disjoint, that is, the set  $fH \cap gH$  is not empty. Then there exists an element  $x \in fH \cap gH$ , and so  $fy_1 = gy_2$  for some  $y_1, y_2 \in H$ . Thus  $g^{-1}f = y_2y_1^{-1} \in H$  and so  $g^{-1}fH = H$ ; hence  $gH = gg^{-1}fH = fH$ , hereby proving the theorem. □

**Corollary 2.3.1.** If  $fH = gH$ , then  $g^{-1}f \in H$ .

### 2.3.2 Lagrange's theorem

Recall the definition of an *order* of a group, denoted  $|G|$ . The next theorem shows the connection between the orders of a group and its subgroup.

**Theorem 2.15** (Lagrange's theorem). Let  $H$  be a subgroup of a finite group  $G$ . Then  $|H|$  divides  $|G|$ , and  $|G|/|H|$  is the number of distinct left (or right) cosets of  $H$  in  $G$ .

*Proof.* From the previous theorem we can write a group  $G$  as a union of the pairwise disjoint coset left of  $H$ . Therefore  $G = g_1H \cup g_2H \cup \cdots \cup g_rH$ . Consequently,

$$|G| = |g_1H| + |g_2H| + \cdots + |g_rH|.$$

It remains to show that  $|g_1H| = |g_2H| = \cdots = |g_rH| = |H|$ . Notice that the map  $x \mapsto g_jx$  is a bijection from  $H$  to  $g_jH$ , and so  $|g_1H| = |g_2H| = \cdots = |g_rH| = |H|$ . Therefore  $|G| = r|H|$  and the results follow. □

The corollaries of Lagrange's theorem are as follows.

**Corollary 2.3.2.** Let  $g$  be an element of a finite group  $G$ . Then the order of  $g$  divides the order of  $G$ .

*Proof.* Let  $d$  be the order of  $g$ . The subgroup  $H = \{e, g, g^1, \dots, g^{d-1}\}$  is a subgroup of order  $d$ . By Lagrange's Theorem,  $|H| \mid |G|$ .  $\square$

**Corollary 2.3.3.** If the order of a group is prime, then it is cyclic.

*Proof.* Let  $G$  be a group with prime order  $p$ . Suppose  $x \in G$ ,  $x \neq e$  and  $H = \langle x \rangle$  be its subgroup. Then  $|H| \mid |G|$ . Since  $|G|$  is prime,  $|H|$  must either be 1 or  $p$ . But  $H$  contains both  $x$  and  $e$ , therefore  $|H| = p$ , that is  $H = G = \langle x \rangle$  as claimed.  $\square$

### 2.3.3 Group of small order (up to 8)

Now we use the result from Lagrange's theorem to classify all groups with order less than 8.

### 2.3.4 Quaternions

### 2.3.5 Fermat-Euler theorem

In this section we shall show some applications of group theory in the study of arithmetic, notably to prove Fermat's theorem and Euler's theorem using tools from group theory. Recall the definition of  $\mathbb{Z}_n$ ,

$$\mathbb{Z}_n = \{0, 1, \dots, n-1\},$$

that is, the set of all remainders after any integer is divided by  $n$ . We are interested in the group structure of  $\mathbb{Z}_n$  with respect to multiplication. A group axiom states that all elements of  $\mathbb{Z}_n$  must have an inverse, that is, there exists an element  $x$  of  $\mathbb{Z}_n$  such that

$$ax \equiv 1 \pmod{n}$$

for all  $a \in \mathbb{Z}_n$ . But not all integer  $n$  satisfied this.

**Example 2.3.1.** Consider  $2 \in \mathbb{Z}_8$ . It does not has an inverse in  $\mathbb{Z}_8$ . Similary 4 and 6 all do not has an inverse. But  $3 \cdot 3 \equiv 1 \pmod{8}$  and  $5 \cdot 5 \equiv 1 \pmod{8}$ , and so they each have inverses mod 8.

Such observation leads to an important result for general set  $\mathbb{Z}_n$ .

**Theorem 2.16.** An element  $a$  of a set  $\mathbb{Z}_n$  has an inverse if and only if it is coprime to  $n$ .

*Proof.* Suppose that  $a$  has an inverse  $a'$  in  $\mathbb{Z}_n$ , then it satisfies the equation

$$aa' \equiv 1 \pmod{n}.$$

Therefore there exists an integer  $k$  such that  $aa' - 1 = kn$ . It follows from Bézout's lemma that  $(a, n) = 1$ .

Conversely, let  $(a, n) = 1$ , then there exists an integer  $k, l$  such that  $ak + nl = 1$ . Thus  $ak \equiv 1 \pmod{n}$ , and so  $a$  has an inverse in  $\mathbb{Z}_n$ .  $\square$

Consequently, the set of all integers coprime to  $n$  forms a group under multiplication. We shall denote them as  $\mathbb{Z}/n\mathbb{Z}$ , using the quotient notation. This motivates the following definition.

**Definition 2.3.1.** The numbers of positive integers up to  $n$ , and are also coprime to  $n$  is equal to  $\phi(n)$ . This is called *Euler's totient function*.

**Corollary 2.3.4.** The order of the group  $\mathbb{Z}/n\mathbb{Z}$  is equal to  $\phi(n)$ .

**Lemma 2.3.1.** For any prime  $p$ , we have  $\phi(p) = p - 1$ .

Now we can prove Euler's theorem using Lagrange's theorem.

**Theorem 2.17** (Euler's theorem). If  $a$  and  $n$  are coprime then

$$a^{\phi(n)} \equiv 1 \pmod{n}.$$

*Proof.* We have seen that the set  $\mathbb{Z}/n\mathbb{Z}$  forms a group and that  $|\mathbb{Z}/n\mathbb{Z}| = \phi(n)$ . Let  $d$  be the order of  $a \in \mathbb{Z}/n\mathbb{Z}$ . Now the set  $\{1, a, a^2, \dots, a^{d-1}\}$  is a subgroup of  $\mathbb{Z}/n\mathbb{Z}$ . By Lagrange's theorem,  $d \mid \phi(n)$ . It then follows that  $a^{\phi(n)} = a^{dk} \equiv 1 \pmod{n}$ , as claimed.  $\square$

The Fermat's theorem is a direct result of Euler's theorem.

**Corollary 2.3.5** (Fermat's theorem). For any prime  $p$  and any integer  $a$ ,

$$a^p \equiv a \pmod{p}.$$

## 2.4 Group actions

This section studies group actions, which involves a "product" between a group and an arbitrary set  $X$  and returns an element of  $X$ . We refer to this by saying that  $G$  *acts* on  $X$ .

A more precise formulation of the above can be given as following:

**Definition 2.4.1.** Let  $X$  be any set and  $G$  be any group, we say that  $G$  acts on  $X$  on the left by the product  $*$ , if for each pair  $(g, x)$  with  $g \in G, x \in X$ , an element  $g * x \in X$  is defined, such that for all  $g, g' \in G$  and all  $x \in X$  the following axioms hold:

1.  $e * x = x$ , and,
2.  $g * (g' * x) = (gg') * x$ .

An alternate formulation when  $G$  acts on  $X$  on the right can also be defined. Our study of group action will rely on this notion and some geometric ideas in the study. Later on we shall apply them to the study of the symmetry groups of regular solids.

**Definition 2.4.2.** Suppose that  $G$  acts on  $X$ . We say that  $x$  is a *fixed point* of  $g$  in  $G$  if  $g * x = x$ , and the set of fixed points of  $g$  is denoted by  $\mathcal{F}(g)$ .

**Definition 2.4.3.** Given  $x$  in  $X$ , the set  $\{g \in G: g * x = x\}$  of elements of  $G$  that fix  $x$  is called the *stabilizer*  $G_x$  of  $x$ .

This set is indeed a group.

**Theorem 2.18.** The stabilizer  $G_x$  is a subgroup of  $G$ .

**Definition 2.4.4.** Suppose that  $G$  acts on  $X$ . Then the subset  $\{g * x: g \in G\}$  of  $X$  is called the *orbit*  $O_x$  of  $x$  under  $G$ . As we could see, it is the set of all images of  $x$  varying  $g$  to every elements of  $G$ .

**Definition 2.4.5.** The action of  $G$  on  $X$  is called *transitive* if for each pair  $x, y$  in  $X$  there exists a  $g$  in  $G$  such that  $g * x = y$ .

**Lemma 2.4.1.** The group  $G$  acts transitively on  $X$  if and only if  $O_x = X$  for one  $x$  in  $X$ .

Note that any two orbits of two elements of  $X$  are either disjoint or equal. Thus the orbits partition  $X$  into equivalence classes.

### 2.4.1 Orbit-stabilizer theorem

The most important result in the section is a variant of Lagrange's theorem.

**Theorem 2.19** (Orbit-stabilizer theorem). If a finite group  $G$  acts on a set  $X$ , then for any  $x \in X$  the order of  $G$  is given by

$$|G| = |O_x| |G_x|,$$

where  $O_x$  is the orbit of  $x$  under  $G$  and  $G_x$  is the stabilizer of  $x$ .

We present two proofs of the theorem, illustrating the power of cosets in group theory.

*1st Proof.* In this proof we let  $G$  acts on the left of  $X$ , the case when  $G$  acts on the right can be argued similarly. We find, from Lagrange's theorem, that  $|G|/|G_x|$  is the number of distinct left cosets of  $G_x$  in  $G$ . It remain to show that, indeed,  $|O_x|$  is equal to  $|G|/|G_x|$ , by finding a bijection between the two sets.

Let  $g$  be any element of  $G$ , and define  $\theta(gG_x) = g * x$ . Thus  $\theta$  is surjective over  $O_x$  by definition of  $O_x$ . Now if  $\theta(gG_x) = \theta(hG_x)$ , then  $g * x = h * x$  which implies  $g^{-1}h \in G_x$ , that is  $g^{-1}hG_x = G_x$ , and so  $gG_x = hG_x$ . Thus  $\theta$  is injective, and this proves the theorem.  $\square$

*2nd Proof.* Take any  $x$  in  $X$  and let the orbit  $O_x$  of  $x$  be  $\{g_1 * x, \dots, g_r * x\}$ , with all of the  $g_i * x$  are distinct. Consider the set  $g_i G_x$ , the left coset of  $G_x$  with respect to  $g_i$ . We will show that the set  $g_i G_x$  and  $g_j G_x$  is disjoint for  $i \neq j$ , and that  $G$  can be decomposed into the union of left cosets of  $G_x$  with respect to the elements of  $O_x$ .

Suppose  $g_i G_x$  and  $g_j G_x$  share at least one element, i.e.  $g_i G_x \cap g_j G_x \neq \emptyset$ , therefore  $g_i h_i = g_j h_j$  for some  $h_i, h_j \in G_x$ . But then

$$\begin{aligned} (g_i h_i) * x &= (g_j h_j) * x \\ g_i * (h_i * x) &= g_j * (h_j * x) \\ g_i * x &= g_j * x, \end{aligned}$$

implying  $i = j$ . Now let  $g$  be any element of  $G$ , we need to find  $g_i$  such that  $g \in g_i G_x$ . Let  $g * x = y$ , then  $y$  is in the orbit of  $x$ , and so there is one  $g_i$  such that  $g_i * x = g * x = y$ . But then we have  $(g_i^{-1}g) * x = x$ , i.e.  $g_i^{-1}g \in G_x$ , which implies  $g_i(g_i^{-1}g) = g \in g_i G_x$ , as claimed.

Thus we can write  $G$  as union of the left cosets of  $G_x$  as  $G = g_1 G_x \cup \cdots \cup g_r G_x$ , this gives

$$|G| = |g_1 G_x| + \cdots + |g_r G_x|.$$

The map  $h \mapsto g_i h$  is obviously a bijection from  $G_x$  to  $g_i G_x$ , and so  $|g_i G_x| = |G_x|$ . Finally we get

$$|G| = r|G_x| = |O_x||G_x|,$$

as needed. □

The above proof gives an alluding idea for the following theorem, which shows that the map  $g * x = y$  can be written in terms of  $g$  and a map that either fixes  $x$  or  $y$ .

**Theorem 2.20.** Suppose that  $G$  acts on  $X$  and that  $g * x = y$ , where  $x, y \in X$  and  $g \in G$ . Then

$$gG_x = \{h \in G : h * x = y\} = G_y g.$$

The following theorem is an important result of orbit-stabilizer theorem in combinatorics.

**Theorem 2.21** (Burnside's lemma). Let  $G$  be a finite group acting on a finite set  $X$ . Then there are  $N$  orbits, where

$$N = \frac{1}{|G|} \sum_{g \in G} |\mathcal{F}(g)| = \frac{1}{|G|} \sum_{x \in X} |G_x|.$$

In particular,  $N$  is the average number of fixed points that an element of  $G$  has.

### 2.4.2 Cayley's theorem

In this section we prove the result by Cayley, which show that, even abstract group is indeed not so abstract.

**Theorem 2.22** (Cayley's theorem). Every finite group is isomorphic to a subgroup of a symmetric group

*Proof.* Let  $g$  be any element of a group  $G$ , and define the map  $\lambda_g: G \rightarrow G$  by the rule  $\lambda_g(a) = ga$ , for all  $a \in G$ . The map is surjective; take any element of  $h$  we have  $g^{-1}h \in G$  and so  $\lambda_g(g^{-1}h) = h$ . It is also injective; let  $\lambda_g(a) = \lambda_g(b)$ , then  $ga = gb$  and so  $a = b$ . This means that  $\lambda_n$  is bijective and thus a permutation of  $G$ . But also the set of all  $\lambda_g$ , ranging  $g$  to all elements of  $G$ , themselves form a group, as the group axiom holds for  $\lambda_g$  as it holds for  $G$ .

Define the map  $\lambda: G \rightarrow \mathcal{P}(G)$  from  $G$  to the set of permutations of  $G$ , by  $\lambda(g) = \lambda_g$ . It is easy to see that  $\lambda$  is a homomorphism; for  $g, h \in G$  we have

$$\lambda_{gh}(a) = (gh)a = g(ha) = \lambda_g(ha) = \lambda_g \lambda_h a,$$

this shows that  $\lambda_{gh} = \lambda_g \lambda_h$ , as it holds for all  $a \in G$ . Thus  $\lambda: G \rightarrow \mathcal{P}(G)$  is a homomorphism.

Finally consider the image  $\text{Im } \lambda$  of  $G$  under  $\lambda$ . It is a subgroup of  $\mathcal{P}(G)$ , precisely since for  $\lambda_g, \lambda_h \in \text{Im } \lambda$ , we have  $\lambda_g \lambda_h^{-1} = \lambda_g \lambda_{h^{-1}} = \lambda_{gh^{-1}} \in \text{Im } \lambda$ . By definition of  $\text{Im } \lambda$ ,  $\lambda$  is an isomorphism from  $G$  to a subgroup  $\text{Im } \lambda$  of a symmetric group  $\mathcal{P}(G)$ .  $\square$

This theorem holds even for infinite group, with extra care for cardinality of  $G$ . Another proof of Cayley's theorem will be given using isomorphism theorems.

**Theorem 2.23.** Any subgroup  $H$  of a group  $G$  is the stabilizer of some group action.

### 2.4.3 Conjugacy classes

In the previous section, we let  $G$  acts on itself in order to prove Cayley's theorem.

### 2.4.4 Cauchy's theorem

## 2.5 Quotient groups

### 2.5.1 Normal subgroups

### 2.5.2 Quotient groups

### 2.5.3 The isomorphism theorem

## 2.6 Matrix groups

### 2.6.1 The general and special linear groups

### 2.6.2 The orthogonal and special orthogonal groups

### 2.6.3 Basis change

## 2.7 Permutations

### 2.7.1 Permutations, Cycles and Transpositions

We have given the definition of permutations before. More importantly, we have show that, generally,  $S_n$  is not abelian, but some elements of  $S_n$  are.

**Example 2.7.1.** Let  $\alpha, \beta \in S_6$ , with

$$\alpha = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 \\ 5 & 2 & 1 & 4 & 3 & 6 \end{pmatrix}, \beta = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 \\ 1 & 6 & 3 & 4 & 5 & 2 \end{pmatrix}.$$

Then

$$\alpha\beta = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 \\ 5 & 6 & 1 & 4 & 3 & 2 \end{pmatrix} = \beta\alpha.$$

We shall now provide a sufficient condition for two permutations to commute.

**Definition 2.7.1.** Any permutations  $\alpha, \beta$  are said to be *disjoint* if, for every  $k$  in  $\{1, 2, \dots, n\}$ , either  $\alpha(k) = k$  or  $\beta(k) = k$ .

**Theorem 2.24.** Two permutations commute if they are disjoint.

*Proof.* Let the two permutations be  $\alpha$  and  $\beta$ . For any  $k \in \{1, \dots, n\}$ , suppose that  $\alpha$  fixes  $k$ , the case for  $\beta$  can be argued similarly.

Let  $\beta(k) = k'$ . Then  $\alpha\beta(k) = \alpha(k')$  and  $\beta\alpha(k) = \beta(k) = k'$ . We shall prove that indeed  $\alpha(k') = k$ . Consider the following two possibility of  $\beta(k')$ .

If  $\beta(k') \neq k'$  then we are done by the premise. So suppose  $\beta(k') = k'$ , but then  $\beta(k') = k' = \beta(k)$ . This implies  $k = k'$  and so  $\alpha(k') = \alpha(k) = k'$  as required.  $\square$

The conventional notation for permutations is unwieldy, especially for large  $n$ . We shall further simplify it, by introducing fixed points.

**Definition 2.7.2.** We call that  $k$  is a *fixed point* of  $\alpha$ , and that  $\alpha$  fixes  $k$ , if  $\alpha(k) = k$ .

And so, by convention, we shall left out any integers fixed by  $\alpha$ . For example, the permutation

$$\alpha = \begin{pmatrix} 1 & 3 \\ 3 & 1 \end{pmatrix}$$

interchanges 1 and 3, and fixes 2. This notation is still too cumbersome for large  $n$ , this drives us to find a new notation. Let us start by noticing that, if we repeatedly apply any permutation  $\alpha$  to any elements in  $\{1, 2, \dots, n\}$ , it must eventually reappear after some finite repetitions. For example, let

$$\alpha = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 5 & 3 & 4 & 2 & 1 \end{pmatrix},$$

then  $\alpha^2(1) = 1, \alpha^3(2) = 1, \alpha^3(3) = 3, \alpha^3(4) = 4$  and  $\alpha^2(5) = 5$ . This is easily proven using the pigeonhole principle. Notice that 1 and 5 form a *cycle* between each other, as  $\alpha$  sends 1 to 5 and also send 5 to 1; this is also the case for 2, 3, 4. The permutation  $\alpha$  sends 2 to 3, 3 to 4, and 4 to 2. This is the motivation to define *cycles*.

**Definition 2.7.3.** A *cycle* between  $n_1, n_2, \dots, n_q$  is the permutation

$$\begin{pmatrix} n_1 & n_2 & \cdots & n_q \\ n_2 & n_3 & \cdots & n_1 \end{pmatrix}.$$

It is denoted by  $(n_1 n_2 \cdots n_q)$ . The cycle is said to be of length  $q$ .

**Definition 2.7.4.** A *transposition* is a cycle of length 2.

The integers  $n_1, n_2, \dots, n_q$  need not be in an increasing order. By inspection, in the above example we have  $\alpha = (1\ 5)(2\ 3\ 4) = (2\ 3\ 4)(1\ 5)$ . We will show that any permutation can be written in this manner, as the compositions of cycles.

**Theorem 2.25.** Any permutation  $\alpha$  in the symmetric group  $S_n$  can be written as a composition of disjoint cycles.

*Proof.* This will employ the similar strategy used above. For any integer  $k \in \{1, \dots, n\}$ , we apply  $\alpha$  repeatedly, and so we have the sequence  $k, \alpha(k), \alpha^2(k), \dots$ ; some elements of this sequence must coincide. Let the two such elements be  $\alpha^p(k) = \alpha^q(k)$ , with  $p < q$ . Thus  $\alpha^{q-p}(k) = k$ . Now there exists a smallest positive number  $u$  such that  $\alpha^u(k) = k$ . The sequence  $k, \alpha(k), \alpha^2(k), \dots, \alpha^{u-1}(k)$  must therefore be distinct.

Now we construct the cycle

$$\gamma_k = (k \ \alpha(k) \ \alpha^2(k) \ \dots \ \alpha^{u-1}(k)).$$

Any two cycles constructed this way are either disjoint or identical, for if  $y = \alpha^d(x)$  for some integer  $d$ , then  $\gamma_x = \gamma_y$ , and we say that  $x$  and  $y$  belong to the same cycle. Continue doing this for all elements of  $\{1, \dots, n\}$ , we will have a collection of cycles  $\{\gamma_{k_1}, \gamma_{k_2}, \dots, \gamma_{k_m}\}$ , all of them are pairwise disjoint.

Now consider the composition  $\gamma_{k_1} \gamma_{k_2} \dots \gamma_{k_m}$ . For any  $x \in \{1, \dots, n\}$ , then  $\gamma_{k_d}(x) = \alpha(x)$  if  $x$  and  $k_d$  belong to the same cycle; else  $\gamma_{k_d}(x) = x$ . And so  $\alpha = \gamma_{k_1} \gamma_{k_2} \dots \gamma_{k_m}$ .  $\square$

The proof above use the idea of constructing the sequence  $k, \alpha k, \alpha^2(k), \dots, \alpha^{u-1}(k)$  of elements of a group, which is indeed the **orbits**. This decomposition is also unique up to the order of  $\gamma_{k_i}$ , and it is called the *standard representation* of  $\alpha$ .

Let's try to decompose a permutation using the theorem. Consider

$$\alpha = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 \\ 3 & 5 & 4 & 1 & 8 & 2 & 7 & 6 \end{pmatrix}$$

with  $\alpha \in S_8$ . The cycle formed by 1 is  $\gamma_1 = (134)$ . Continuing this, we have the collection  $\{(134), (2586), (7)\}$ , and the standard representation of  $\alpha$  is  $(134)(2586)(7)$ . One can drop the single cycle (7) and so

$$\alpha = (134)(2586).$$

Finally, consider a cycle  $\alpha$  of length  $n$ . Note that  $\alpha^n = \iota$ . Furthermore, for any positive integer  $d$ ,

$$\alpha^d = (\gamma_{k_1} \gamma_{k_2} \dots \gamma_{k_m})^d = \gamma_{k_1}^d \gamma_{k_2}^d \dots \gamma_{k_m}^d,$$

since all cycles commute. It follows that if  $d$  is the least common multiple of  $n_{k_1}, n_{k_2}, \dots, n_{k_m}$ , where  $n_{k_i}$  is the length of  $\gamma_{k_i}$ , then  $\alpha^d = \iota$ . The least common multiple is indeed the smallest positive integer with such property.

## Vectors and Matrices

### 3.1 Complex Numbers

#### 3.1.1 Complex logarithm

### 3.2 Vectors

#### 3.2.1 Vector Algebra in $\mathbb{R}^3$

This section will review algebra of vectors in  $\mathbb{R}^3$ . They are usually regarded as an arrow, one with *dimension* and *length*. Starting from two points inside the space  $\mathbb{R}^3$ , namely  $P(p_1, p_2, p_3)$  and  $Q(q_1, q_2, q_3)$  we may draw a vector from  $P$  to  $Q$ , and is expressed by

$$\overrightarrow{PQ} = (q_1 - p_1, q_2 - p_2, q_3 - p_3).$$

Generally let  $\mathbf{u} = (u_1, u_2, u_3)$ . This vector can also be written as a sum of unit vectors laying on the axis. Those unit vectors are

$$\mathbf{i} = (1, 0, 0), \quad \mathbf{j} = (0, 1, 0), \quad \text{and} \quad \mathbf{k} = (0, 0, 1).$$

And  $\mathbf{u} = u_1\mathbf{i} + u_2\mathbf{j} + u_3\mathbf{k}$ . We can multiply vectors by a scalar, which is a real number, by

$$\mu\mathbf{u} = (\mu u_1, \mu u_2, \mu u_3).$$

The usual properties of vectors should be familiar, that is  $\mu(\mathbf{u} + \mathbf{v}) = \mu\mathbf{u} + \mu\mathbf{v}$ ,  $(\mu + \lambda)\mathbf{u} = \mu\mathbf{u} + \lambda\mathbf{u}$ , and  $(\mu\lambda)\mathbf{u} = \mu(\lambda\mathbf{u})$ .

#### 3.2.2 Vectors in $\mathbb{R}^n$ and $\mathbb{C}^n$

Let us consider vectors in  $\mathbb{R}^n$ , the natural generalisation of  $\mathbb{R}^3$ .

**Definition 3.2.1.** Using the standard basis  $e_1, \dots, e_n$  of  $\mathbb{R}^n$ , if  $x = \sum_j x_j e_j$  and  $y = \sum_j y_j e_j$ , we write

$$x \cdot y = \sum_{j=1}^n x_j y_j, \quad \|x\|^2 = x \cdot x = \sum_{j=1}^n x_j^2,$$

and  $x \perp y$  when  $x \cdot y = 0$ .

Note that  $\|x\| = \|-x\|$ . The distance  $\|x - y\|$  between the points  $x$  and  $y$  is given by the natural extension of Pythagoras' theorem, and importantly, satisfies the *triangle inequality*.

$$\|x - z\| \leq \|x - y\| + \|y - z\|. \quad (3.1)$$

To prove this assertion, it is sufficient to show that  $|x \cdot y| \leq \|x\|\|y\|$ , so that we have  $\|x + y\| \leq \|x\| + \|y\|$ , which readily implies the triangle inequality. Thus we seek to prove

**Theorem 3.1** (the Cauchy-Schwarz inequality). For all  $x, y \in \mathbb{R}^n$ ,

$$|x \cdot y| \leq \|x\|\|y\|. \quad (3.2)$$

The equality holds if and only if  $\|x\|y = \pm\|y\|x$ , i.e. one vector is a multiple of one another.

*Proof.* Let  $x = (x_1, \dots, x_n)$  and  $y = (y_1, \dots, y_n)$ . The equation holds true when  $x = 0$  and when  $y = 0$ . So we assume that  $\|x\|\|y\| > 0$ .

Consider the equation

$$0 \leq \sum_{j=1}^n (\|x\|y_j - \|y\|x_j)^2 = 2\|x\|\|y\| (\|x\|\|y\| - xy),$$

so  $x \cdot y \leq \|x\|\|y\|$ ; similarly, put  $-x$  as  $x$  and we have  $-x \cdot y \leq \|x\|\|y\|$ . Therefore  $|x \cdot y| \leq \|x\|\|y\|$ . Equality holds if  $\sum_{j=1}^n (\|x\|y_j - \|y\|x_j)^2$  or  $\sum_{j=1}^n (\|x\|y_j + \|y\|x_j)^2$  is equal to zero, which implies  $\|x\|y = \pm\|y\|x$ .  $\square$

Now we are sufficiently equipped with the tool to prove the triangle inequality for general  $\mathbb{R}^n$  space.

**Theorem 3.2** (The triangle inequality for  $\mathbb{R}^n$ ). For all  $x, y, z$  in  $\mathbb{R}^n$ ,

$$\|x - z\| \leq \|x - y\| + \|y - z\|. \quad (3.3)$$

*Proof.* Set  $a = x - y$  and  $b = y - z$ . The inequality is equivalent to  $\|a + b\| \leq \|a\| + \|b\|$ , which we seek to prove. Note that

$$\begin{aligned} \|a + b\|^2 &= (a + b) \cdot (a + b) = \|a\|^2 + \|b\|^2 + 2a \cdot b \\ &\leq \|a\|^2 + \|b\|^2 + 2\|a\|\|b\| = (\|a\| + \|b\|)^2. \end{aligned}$$

Taking square root on both sides we arrive at  $\|a + b\| \leq \|a\| + \|b\|$ .  $\square$

### 3.2.3 Concepts in linear algebra

We shall begin with a concept of a basis.

**Definition 3.2.2.** The set of vectors  $v_1, \dots, v_n$  of vectors in a vector space  $V$  is called a *basis* of  $V$  if, for every  $v$  in  $V$ , there exists unique scalars  $\lambda_j$  such that  $\sum_{j=1}^n \lambda_j v_j = v$ .

Note that the scalars must exist, and are unique for any  $v$ . The following theorem follows readily.

**Theorem 3.3.** For any vector space  $V$ , if  $v_1, \dots, v_n$  and  $w_1, \dots, w_m$  both form the bases of  $V$ , then  $n = m$ .

The above theorem allows us to meaningfully assign *dimension* to non-trivial vector spaces  $V$ , which is the number of elements in any basis of  $V$ , if it is finite. This is called the dimension of  $V$ .

**Definition 3.2.3.** Let  $V$  be a vector space. We say that  $V$  is a *finite dimensional* vector space, or  $\dim V$  is finite, if the basis of  $V$  is finite. Then we take  $\dim V$  as the number of elements of the basis of  $V$ . If  $V = \{0\}$  we put  $\dim V = 0$ . If the basis of  $V$  is infinite, we say that  $V$  is infinite dimensional.

The following definition captures the two essential properties of basis.

**Definition 3.2.4.** Let  $S = \{v_1, \dots, v_k\}$  be a finite set of vectors in  $V$ . The set  $\text{span}(S)$  is the set of all linear combination of elements of  $S$ . If  $\text{span}(S) = V$ , we say that  $S$  *spans*  $V$ , or  $S$  *generates*  $V$ .

**Definition 3.2.5.** The set  $S = \{v_1, \dots, v_k\}$  is *linearly independent* if, for all scalars  $\lambda_j, \mu_j$ ,

$$\sum_j \lambda_j v_j = \sum_j \mu_j v_j \text{ implies } \lambda_j = \mu_j \text{ for all } j.$$

Otherwise we say that  $S$  is *linearly dependent*.

**Theorem 3.4.** The set  $S$  forms a basis of  $V$  if and only if it spans  $V$  and is linearly independent.

### 3.2.4 Suffix notation

### 3.2.5 Vector product and triple product

### 3.2.6 Solution of linear vector equations

### 3.2.7 Applications

## 3.3 Matrices

**Definition 3.3.1.** An  $n \times m$  matrix is an array of numbers of the form

$$\begin{pmatrix} a_{11} & a_{12} & \cdots & a_{1m} \\ a_{21} & a_{22} & \cdots & a_{2m} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nm} \end{pmatrix}.$$

Sometimes it will be denoted by  $(a_{ij})$ , where  $a_{ij}$  is the general element of the matrix, the index  $i$  stands for the *row* and  $j$  for the *column* of the element.

**Definition 3.3.2.** An  $n \times n$  matrix is called a *square* matrix.

### 3.3.1 Algebra of matrices

### 3.3.2 Determinant and trace

**Theorem 3.5.** The *trace* of an  $n \times n$  matrix  $\mathbf{A}$ , denoted  $\text{tr } \mathbf{A}$  is the sum of its diagonal entries, that is

$$\text{tr } \mathbf{A} = \sum_{i=1}^n a_{ii} = a_{11} + a_{22} + \cdots + a_{nn}.$$

**Theorem 3.6.** It is evident that, for two square matrices  $\mathbf{A}$  and  $\mathbf{B}$  with same dimension,

$$\text{tr}(\mathbf{A} + \mathbf{B}) = \text{tr } \mathbf{A} + \text{tr } \mathbf{B}.$$

### 3.3.3 Matrix as linear transformation

We start with the definition of linear transformations.

**Definition 3.3.3.** A map  $\alpha: V \rightarrow W$  between vector spaces  $V$  and  $W$  is *linear* if, for all scalars  $\lambda_1, \dots, \lambda_n$ , and all vectors  $v_1, \dots, v_n$ ,

$$\alpha(\lambda_1 v_1 + \cdots + \lambda_n v_n) = \lambda_1 \alpha(v_1) + \cdots + \lambda_n \alpha(v_n).$$

If  $\alpha$  is linear we say that it is a *linear transformation*, or a *linear map*, if for all scalars  $\lambda$  and all vectors  $u$  and  $v$ ,  $\alpha(\lambda x) = \lambda \alpha(x)$  and  $\alpha(x + y) = \alpha(x) + \alpha(y)$ .

The two definitions are equivalent.

**3.4 Eigenvalues and Eigenvectors**

# Chapter 4

## Differential Equations

### 4.1 Basic Calculus

#### 4.1.1 Differentiation

**Definition 4.1.1.** The derivative of a function  $f(x)$  with respect to  $x$ , is the rate of change of  $f(x)$  at  $x$ , is defined as

$$\frac{df}{dx} = \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h}. \quad (4.1)$$

The function  $f$  is differentiable at  $x$  if the limit exists. We may write  $\frac{df}{dx} = f'(x)$ . And more generally,  $\frac{d^n}{dx^n} f(x) = f^{(n)}(x)$  is the  $n$ -th derivative of  $f$ .

We shall adopt the convention that  $f'(x)$  is the derivative with respect to the argument, or variable, of the function. For example,  $f'(2x)$  is to be view as a derivative of  $f$  with respect to  $2x$ , that is,  $f'(2x) = \frac{df}{d(2x)}$ .

#### 4.1.2 Big $O$ and small $o$ notation

**Definition 4.1.2.** We say that  $f(x) = o(g(x))$  as  $x \rightarrow x_0$  if  $\lim_{x \rightarrow x_0} \frac{f(x)}{g(x)} = 0$ . That is,  $f(x)$  is much *smaller* than  $g(x)$ .

**Definition 4.1.3.** We say that  $f(x) = O(g(x))$  as  $x \rightarrow x_0$  if  $\frac{f(x)}{g(x)}$  is bounded as  $x \rightarrow x_0$ . That is,  $f(x)$  is as big as  $g(x)$ .

The definition of  $O$  does not requires that  $\lim_{x \rightarrow x_0} \frac{f(x)}{g(x)}$  exists;  $\sin x = O(1)$  as  $x \rightarrow \infty$  but  $\lim_{x \rightarrow \infty} \sin x$  does not exists.

**Theorem 4.1.** Let  $f$  be a function differentiable at  $x_0$ , then

$$f(x_0 + h) = f(x_0) + f'(x_0)h + o(h) \quad (4.2)$$

as  $h \rightarrow 0$ .

*Proof.* From the definition of differentiation and  $o$ ,

$$f'(x_0) = \frac{f(x_0 + h) - f(x_0)}{h} - \frac{o(h)}{h}. \quad (4.3)$$

The result follows. □

### 4.1.3 Rules of differentiation

**Theorem 4.2** (Chain rule). Let  $f(x) = F(g(x))$ ,  $F$  is differentiable at  $g(x)$  and  $g$  is differentiable at  $x$ , then

$$\frac{df}{dx} = \frac{dF}{dg} \frac{dg}{dx}.$$

*Proof.* We have

$$\begin{aligned} \frac{df}{dx} &= \lim_{h \rightarrow 0} \frac{F(g(x+h)) - F(g(x))}{h} \\ &= \lim_{h \rightarrow 0} \frac{F(g(x) + hg'(x) + o(h)) - F(g(x))}{h} \\ &= \lim_{h \rightarrow 0} \frac{\quad}{den} \end{aligned}$$

## Analysis I

A rigorous theory of mathematical analysis must take an axiomatic approach as its foundation. Thus it is preferable to start from the construction of real numbers, and then discover their properties, as not to take them for granted. This foundational rigour is, fortunately, available for us by Dedekind and his model for the real number.

What are the essential properties of  $\mathbb{R}$ ? We have learnt that  $\mathbb{R}$  is a field, with the usual addition and multiplication; the usual subtraction and division is also possible.

Secondly, there is a *total order* on  $\mathbb{R}$ , that is, if  $x, y \in \mathbb{R}$  then either  $x \leq y$  or  $y \leq x$ , and only  $x = y$  when both condition are satisfied. Furthermore, if  $x \leq y$  and  $y \leq z$  then  $x \leq z$ . This means  $\mathbb{R}$  is an *ordered field* and that is, if  $x \leq y$  then  $x + z \leq y + z$ , and if  $w \geq 0$  then  $xw \leq yw$ .

Of course,  $\mathbb{Q}$  is also an ordered field, but it is not *complete*. This is the most important property of  $\mathbb{R}$  to keep in mind. Let's start by a notion of an *upper bound*. If  $A$  is a non-empty subset of  $\mathbb{R}$  and  $b \in \mathbb{R}$ , then  $b$  is an upper bound for  $A$  if  $b \geq a$  for all  $a \in A$ . By saying that  $\mathbb{R}$  is complete, this means that, if  $A$  is a non-empty set of  $\mathbb{R}$  with an upper bound, then  $A$  has a *least upper bound*, or *supremum*  $\sup A$ . This translates to, for any upper bound  $b$  of a set  $A \subset \mathbb{R}$ , should it exist, we have  $\sup A \leq b$ .

Another central theme of analysis regards *absolute value*, that is the function

$$|x| = \begin{cases} x & \text{if } x \geq 0 \\ 0 & \text{if } x = 0 \\ -x & \text{if } x \leq 0 \end{cases} . \quad (5.1)$$

Note that  $|x - y| = |y - x|$  and  $|x| \geq 0$  for all  $x \in \mathbb{R}$ .

**Theorem 5.1.** For all  $x, y \in \mathbb{R}$ ,  $|x + y| \leq |x| + |y|$ , with equality when  $xy \geq 0$ .

*Proof.* Trivial proof by case. □

**Theorem 5.2.** (Triangle Inequality) For all  $x, y, z \in \mathbb{R}$ , we have

$$|x - z| \leq |x - y| + |y - z|. \quad (5.2)$$

*Proof.* Simply substitute  $x - y$  and  $y - z$  in place of  $x$  and  $y$ , respectively. □

## 5.1 Limit and Convergences

Let's start with sequences.

### 5.1.1 Series and sequences in $\mathbb{R}$ and $\mathbb{C}$

**Definition 5.1.1.** A *sequence* is an ordered list of number, with a natural number  $n$  corresponding to the  $n$ th term in the sequence.

**Definition 5.1.2.** A sequence  $s_n$  is a *null sequence* if, to every positive number  $\epsilon$ , there corresponds an integer  $N$  such that

$$|s_n| < \epsilon \text{ for all values of } n \text{ greater than } N.$$

We can adapt the definition to any sequence whose terms approach any number  $s$ .

**Definition 5.1.3.** A sequence  $s_n$  is said to tend to the limit  $s$  if, given any positive number  $\epsilon$ , there is an integer  $N$  (depending on  $\epsilon$ ) such that

$$|s_n - s| < \epsilon \text{ for all } n > N.$$

We then write  $\lim s_n = s$ .

A more clear notation  $\lim_{n \rightarrow \infty} s_n = s$  can be given.

*Note.* 1. Clearly,  $\lim s_n = s$  if and only if  $s_n - s$  is a null sequence.

2. The inequality  $|s_n - s| < \epsilon$  is equivalent to the two inequalities

$$s - \epsilon < s_n < s + \epsilon.$$

This is clear that  $s_n$  is bounded.

3. A short notation  $s_n \rightarrow s$  stands for  $\lim s_n = s$ . A further symbolism for the above definition may be given:

$$s_n \rightarrow s \text{ if } \epsilon > 0; \quad \exists N. |s_n - s| < \epsilon \text{ for all } n > N.$$

If limits exist, they are unique.

**Theorem 5.3.** If  $a_n \rightarrow s$  as  $n \rightarrow \infty$  and  $a_n \rightarrow l$  as  $n \rightarrow \infty$ , then  $s = l$ .

*Proof.* We will prove this theorem by contradiction. Suppose  $s \neq l$ . Let  $\epsilon = |s - l|/3 > 0$ . There exists  $n_0$  such that  $|a_n - s| < \epsilon$  for  $n \geq n_0$ , and there exists  $m_0$  such that  $|a_n - l| < \epsilon$  for  $n \geq m_0$ . Let  $N = \max(n_0, m_0)$ . Then if  $n \geq N$ ,

$$|l - s| \leq |a_n - l| + |a_n - s| < 2\epsilon = 2|l - s|/3,$$

a contradiction. □

We have discussed on upper bound and lower bound of a set, it is time to introduce a notion of *boundedness*, and expand it to those of sequences in general.

**Definition 5.1.4.** A subset  $A$  of  $\mathbb{R}$  is *bounded* if it is bounded above and bounded below. A sequence  $s_n$  is bounded if the set  $\{s_n : n \in \mathbb{Z}^+\}$  is bounded.

**Theorem 5.4.** If a sequence tends to a limit, then it is bounded.

*Proof.* Let the sequence  $a_n$  tends to the limit  $l$ . We choose an arbitrary  $\epsilon$  so that for any  $n \geq n_0$  the difference  $|a_n - l|$  is less than  $\epsilon$ .

Let  $\epsilon = 1$ , so that  $|a_n - l| < 1$  for all  $n \geq n_0$ . Choose

$$M = \max\{|a_1|, |a_2|, \dots, |a_{n_0}|, |l| + 1\}.$$

Then for all  $n \geq n_0$   $|a_n| \leq |a_n - l| + |l| < 1 + |l|$ . Clearly,  $|a_n| \leq M$  and we are set.  $\square$

Note that the converse of the theorem might not be true; if a sequence is bounded, then it *might not* tends to a limit. Consider the sequence  $a_n = \cos n\pi$ . It is bounded, but  $a_n$  does not tend to a limit.

**Theorem 5.5.** Suppose that  $a_n$  is an increasing sequence of real numbers. If it is bounded then  $a_n \rightarrow \sup\{a_n : n \in \mathbb{Z}^+\}$  as  $n \rightarrow \infty$ ; otherwise  $a_n \rightarrow +\infty$ .

Similarly, for any decreasing sequence  $a_n$ , if it is bounded, then  $a_n \rightarrow \inf\{a_n : n \in \mathbb{Z}^+\}$ ; otherwise  $a_n \rightarrow -\infty$ .

One sequence worth considering is the sequence  $a_n = r^n$ . The convergence of the sequence depends on the value of  $r$ .

1. If  $r = 1$ , then  $a_n \rightarrow 1$ , and if  $r = 0$  then  $a_n \rightarrow 0$ .
2. If  $r > 1$ , then  $r = 1 + k$  for some  $k > 0$ , so we have

$$a_n = (1 + k)^n > 1 + kn$$

by considering the first two terms in the binomial expansion. And so  $a_n \rightarrow +\infty$ .

3. If  $0 < r < 1$ , then  $r^{-1} = 1 + l > 1$  with  $l > 0$ , thus

$$0 < a_n = \frac{1}{(1 + l)^n} < \frac{1}{1 + nl}.$$

As  $n \rightarrow \infty$ ,  $1/(1 + nl) \rightarrow 0$  and therefore  $a_n \rightarrow 0$ .

4. If  $-1 < r < 0$ , set  $s = -r$ , so that  $0 < s < 1$ , it follows that  $s^n \rightarrow 0$  as  $n \rightarrow \infty$ , and therefore  $a_n = (-s)^n \rightarrow 0$ .
5. If  $r = -1$ , then  $a_n$  takes the values  $-1$  and  $1$  alternatively, and so it oscillates finitely.
6. If  $r < -1$ , set  $s = -r$ , then  $s^n \rightarrow \infty$ . And so  $a_n = (-s)^n$  takes numerically increasing values alternating between negative and positive. That is to say  $a_n$  oscillates infinitely.

Another proof of convergence of  $a_n = r^n$  when  $0 < r < 1$  can be given, as follows: the sequence  $r^n$  is decreasing and bounded (by 0), therefore it tends to  $\inf\{r^n : n \in \mathbb{Z}^+\}$ , which is 0.

### 5.1.2 Sums, products and quotients

We start with important theorem of sums and products of null sequence.

**Theorem 5.6.** If  $s_n$  and  $t_n$  are null sequences, so is  $s_n + t_n$ .

**Theorem 5.7.** If  $s_n$  is a null sequence and  $t_n$  is a bounded sequence, then  $s_n t_n$  is a null sequence.

**Corollary 5.1.1.** If  $s_n$  is a null sequence and  $c$  is a constant, then  $cs_n$  is a null sequence.

We then now extend the results to general sequences.

**Theorem 5.8.** If  $s_n \rightarrow s$  and  $t_n \rightarrow t$ , then

1.  $s_n + t_n \rightarrow s + t$ ,
2.  $s_n t_n \rightarrow st$ .

**Theorem 5.9.** If  $s_n \rightarrow s$  and  $t_n \rightarrow t$  with  $t \neq 0$ , then

$$\frac{s_n}{t_n} \rightarrow \frac{s}{t}$$

**Theorem 5.10.** If  $s_n \rightarrow s$  and  $t_n \rightarrow t$  and  $s_n \leq t_n$  for all  $n$ , then  $s \leq t$ .

**Theorem 5.11.** If  $s_n \rightarrow s$  and  $s_{n_k}$  is a subsequence, then  $s_{n_k} \rightarrow s$ .

### 5.1.3 Absolute convergence

### 5.1.4 Bolzano-Weierstrass theorem

**Theorem 5.12.** (Bolzano-Weierstrass theorem) Suppose that  $a_n$  is a bounded sequence of real numbers. There there is a subsequence  $a_{n_k}$  which converges.

## Metric and Topological Spaces

### 10.1 Metrics

#### 10.1.1 Definition and examples

We extend the notion of continuity, first to  $\mathbb{R}^2$ . But let's start from the case of continuity in  $\mathbb{R}$ . What does it mean for  $f$  to be continuous at  $a$ ? One might start from the definition that

$$\forall \epsilon > 0; \quad \exists \delta > 0. |f(x) - f(a)| < \epsilon \text{ for } |x - a| < \delta.$$

That is, we can make the distance between  $f(x)$  and  $f(a)$  as small as we want, by choosing  $x$  so that the distance  $|x - a|$  between  $x$  and  $a$  is sufficiently small. What about  $\mathbb{R}^2$ ?

Since we know that, for two points  $(x, y)$  and  $(a, b)$  in  $\mathbb{R}^2$  the distance between them is equal to  $\sqrt{(x - a)^2 + (y - b)^2}$ , and because both  $f(x, y)$  and  $f(a, b)$  are real numbers, it follows that  $|f(x, y) - f(a, b)|$  exists and is the distance between  $f(x, y)$  and  $f(a, b)$ . We then have the condition for continuity of  $f$  in  $\mathbb{R}^2$ , that is, we can make the distance between  $f(x, y)$  and  $f(a, b)$  as small as needed, for any  $(x, y)$  such that its distance from  $(a, b)$  is small enough.

In formal  $(\epsilon, \delta)$ -definition,  $f: \mathbb{R}^2 \rightarrow \mathbb{R}$  is continuous at  $(a, b)$  if given  $\epsilon > 0$  we can find  $\delta > 0$  such that  $|f(x, y) - f(a, b)| < \epsilon$  for all  $(x, y) \in \mathbb{R}^2$  satisfying  $\sqrt{(x - a)^2 + (y - b)^2} < \delta$ .

Thus in order to generalised the idea of continuity to  $\mathbb{R}^n$ , we need to extend the idea of *distance* between two points. We see that in case  $n = 3$  the distance between two points is  $\sqrt{(x_1 - a_1)^2 + (x_2 - a_2)^2 + (x_3 - a_3)^2}$ , as for the case when  $n = 2$ . The case when  $n = 1$  is given by  $|x - a| = \sqrt{(x - a)^2}$ . The following definition for the distance between  $(x_1, \dots, x_n)$  and  $(a_1, \dots, a_n)$  is then natural:

$$\sqrt{\sum_{i=1}^n (x_i - a_i)^2}.$$

This is called the *Euclidean distance*.

**Definition 10.1.1.** A function  $f: \mathbb{R}^n \rightarrow \mathbb{R}$  is *continous* at a point  $a = (a_1, a_2, \dots, a_n) \in \mathbb{R}^n$ , if given  $\epsilon > 0$  there exists  $\delta > 0$  such that  $|f(x) - f(a)| < \epsilon$  for every  $x = (x_1, x_2, \dots, x_n)$

satisfying

$$\sqrt{\sum_{i=1}^n (x_i - a_i)^2} < \delta.$$

In another direction to generalisation, the idea of extending continuity for any map  $f: X \rightarrow Y$  is plausible, given that the notion of distance between two elements of  $X$  is adequate, as is the case for two elements of  $Y$ . Such notion would then be a map  $d: X \times X \rightarrow \mathbb{R}$ . This is called the *metric*  $d$ . We take some properties, taken from our familiar Euclidean distance, and chosen as axioms for general metric space.

**Definition 10.1.2.** A metric space consists of a non-empty set  $X$  with a function, called a metric,  $d: X \times X \rightarrow \mathbb{R}$ , such that the following properties hold:

1. for all  $x, y \in X$ ,  $d(x, y) \geq 0$ ; and  $d(x, y) = 0$  if and only if  $x = y$ ,
2. for all  $x, y \in X$ ,  $d(x, y) = d(y, x)$ , and,
3. for all  $x, y, z \in X$ ,  $d(x, y) \leq d(x, z) + d(z, y)$ .

**Example 10.1.1.** The Euclidean  $n$ -space  $(\mathbb{R}^n, d_2)$  where for two elements  $x = (x_1, \dots, x_n), y = (y_1, \dots, y_n)$ ,

$$d_2(x, y) = \sqrt{\sum_{i=1}^n (x_i - y_i)^2}.$$

One can verify that  $d_2$  satisfies all three axiom. The first two is easy to see, but for the third axiom one need the Cauchy-Schwarz inequality.

**Example 10.1.2.** Let  $X$  be any non-empty subset and define  $d$  by

$$d(x, y) = \begin{cases} 1, & x = y, \\ 0, & x \neq y. \end{cases}$$

This is called *the discrete metric*.

**Definition 10.1.3.** Suppose that  $(X, d)$  is a metric space and that  $A$  is a non-empty subset of  $X$ . Let  $d_A: A \times A \rightarrow \mathbb{R}$  be the restriction of  $d$  to  $A \times A$ . The metric space axioms holds for  $d_A$  also. The metric space  $(A, d_A)$  is called a metric subspace of  $(X, d)$  and  $d_A$  is called the metric on  $A$  induced by  $d$ .

If we have metric spaces  $(X, d)$ ,  $(X', d')$ , and a map  $f: X \rightarrow X'$  then for any subset  $A \subset X$  and  $a \in A$  we can talk about continuity of  $f|_A$  at  $a$ .

**Example 10.1.3.** Consider  $f: \mathbb{R} \rightarrow \mathbb{R}$  given by

$$f(x) = \begin{cases} 0, & x \in \mathbb{Q}, \\ 1, & x \notin \mathbb{Q}. \end{cases}$$

Note that  $f|_{\mathbb{Q}}: \mathbb{Q} \rightarrow \mathbb{R}$  is constant and also continuous, whereas  $f$  is not continuous at any point.

The two following examples are metrics in number theory and group theory.

**Example 10.1.4.** Let  $p$  be a fixed prime number, and define  $d: \mathbb{Z} \times \mathbb{Z} \rightarrow \mathbb{R}$  by  $d(m, m) = 0$ , and for distinct  $m, n$  let  $d(m, n) = 1/r$ , where  $p^{r-1}$  is the highest power of  $p$  which divides  $m - n$ .

**Example 10.1.5.** Suppose  $G$  is a finitely generated group and  $\mathcal{A}$  is a generating set for  $G$ . Let  $F(\mathcal{A})$  be the free group on  $\mathcal{A}$ , and let  $p: F(\mathcal{A}) \rightarrow G$  be the natural map. The word metric  $d_{\mathcal{A}}$  on  $G$  associated to  $\mathcal{A}$  is defined as follows: for  $g_1, g_2 \in G$  let  $d_{\mathcal{A}}(g_1, g_2)$  be the length of the shortest word in  $p^{-1}(g_1^{-1}g_2)$ .

## 10.1.2 Limits and continuity

In the previous section we define a metric, an extension of distance to any set, in order to generalise our idea of continuity. We now propose a definition of continuity, suitable for any set.

**Definition 10.1.4.** Suppose that  $(X, d_X)$  and  $(Y, d_Y)$  are metric spaces and let  $f: X \rightarrow Y$  be a map.

1. We say  $f$  is continuous at  $x_0 \in X$  if given  $\epsilon > 0$ , there exists  $\delta > 0$  such that  $d_Y(f(x), f(x_0)) < \epsilon$  whenever  $d_X(x, x_0) < \delta$ .
2. We say  $f$  is continuous if  $f$  is continuous at every  $x \in X$ .

We might say that  $f$  is  $(d_X, d_Y)$ -continuous to emphasise on the metrics  $d_X$  and  $d_Y$ .

## Groups, Rings and Modules

### 13.1 Groups

We have gone into details of groups in Part IA.

#### 13.1.1 Basics concepts

#### 13.1.2 Normal subgroups

#### 13.1.3 Sylow subgroups and Sylow theorems

### 13.2 Rings

#### 13.2.1 Definition

Rings are abstraction of systems with addition and multiplication. The prototype of rings are the set  $\mathbb{Z}$  of integers.

We define the general notion of ring in a similar way. We say that a set  $R$  with two operations, addition and multiplication, denoted  $x + y$  and  $x \cdot y$ , respectively. We write  $x \cdot y$  as  $xy$  for comprehensiveness.

**Definition 13.2.1.** A set  $R$  is a ring if the following properties are satisfied:

1.  $R$  forms an abelian group under addition.
2.  $R$  forms a monoid under multiplication.
3. The distributive laws hold true, i.e.

$$x(y + z) = xy + xz, (y + z)x = yx + zx.$$

## Complex Analysis

### 15.1 Analytic Functions

#### 15.1.1 Complex differentiation

We first start with the basic definition of limit for complex functions.

**Definition 15.1.1.** The function  $f$  is said to have the limit  $A$  as  $x$  tends to  $a$ ,

$$\lim_{x \rightarrow a} f(x) = A,$$

if and only if the following is true:

For every  $\epsilon > 0$  there exists a real number  $\delta > 0$  with the property that  $|f(x) - A| < \epsilon$  for all values of  $x$  such that  $|x - a| < \delta$  and  $x \neq a$ .

Note that the definition is the same to those of limit of a real function. This is possible since the absolute function admits both real and complex numbers. The well-known results concerning the limit of a sum, a product and a quotient of limits is preserved.

Note that we also have the following properties:

1.  $\lim_{x \rightarrow a} \overline{f(x)} = \overline{A}$ .
2.  $\lim_{x \rightarrow a} \Re f(x) = \Re A$ .
3.  $\lim_{x \rightarrow a} \Im f(x) = \Im A$ .

**Definition 15.1.2.** The function  $f$  is said to be continuous if  $\lim_{x \rightarrow a} f(x) = f(a)$ .

**Definition 15.1.3.** A complex-valued function  $f$  defined on an *open* subset  $G$  of  $\mathbb{C}$  is differentiable at  $z \in G$  if

$$\lim_{h \rightarrow 0} \frac{f(z+h) - f(z)}{h}$$

exists. When the limit does exist it is denoted by  $f'(z)$ .

Let us consider when  $f$  is a real function, that is  $f(z)$  is real for all value of  $z$ . Then the quotient

$$\frac{f(z+h) - f(z)}{h}$$

is real if  $h$  is real; and if  $h = ia$  is purely imaginary, then

$$\frac{f(z+ia) - f(z)}{ia}$$

is imaginary. It follows that  $f'(z) = 0$  for all  $z$  in the domain. Thus a real function of a complex variable must either has the derivative zero, else the derivative does not exist.
